# Section :Data conversions

Slide intentionally left empty

# Data Conversions, Overflow and underflow

Technically , all variables in an expression should be of the same type

int + int - int \* int + int

double + double - double \* double + double

## Overflow and Underflow

```
//Overflow and overflow.
```

```
unsigned char char_var {55};  
char_var = 261; // Store in more than can fit in memory  
char_var = -1;  // Store in a negative number
```

Slide intentionally left empty

# Implicit Data Conversions

Technically , all variables in an expression should be of the same type

int + int - int \* int + int

double + double - double \* double + double

Conversions done by the compiler without your involvement

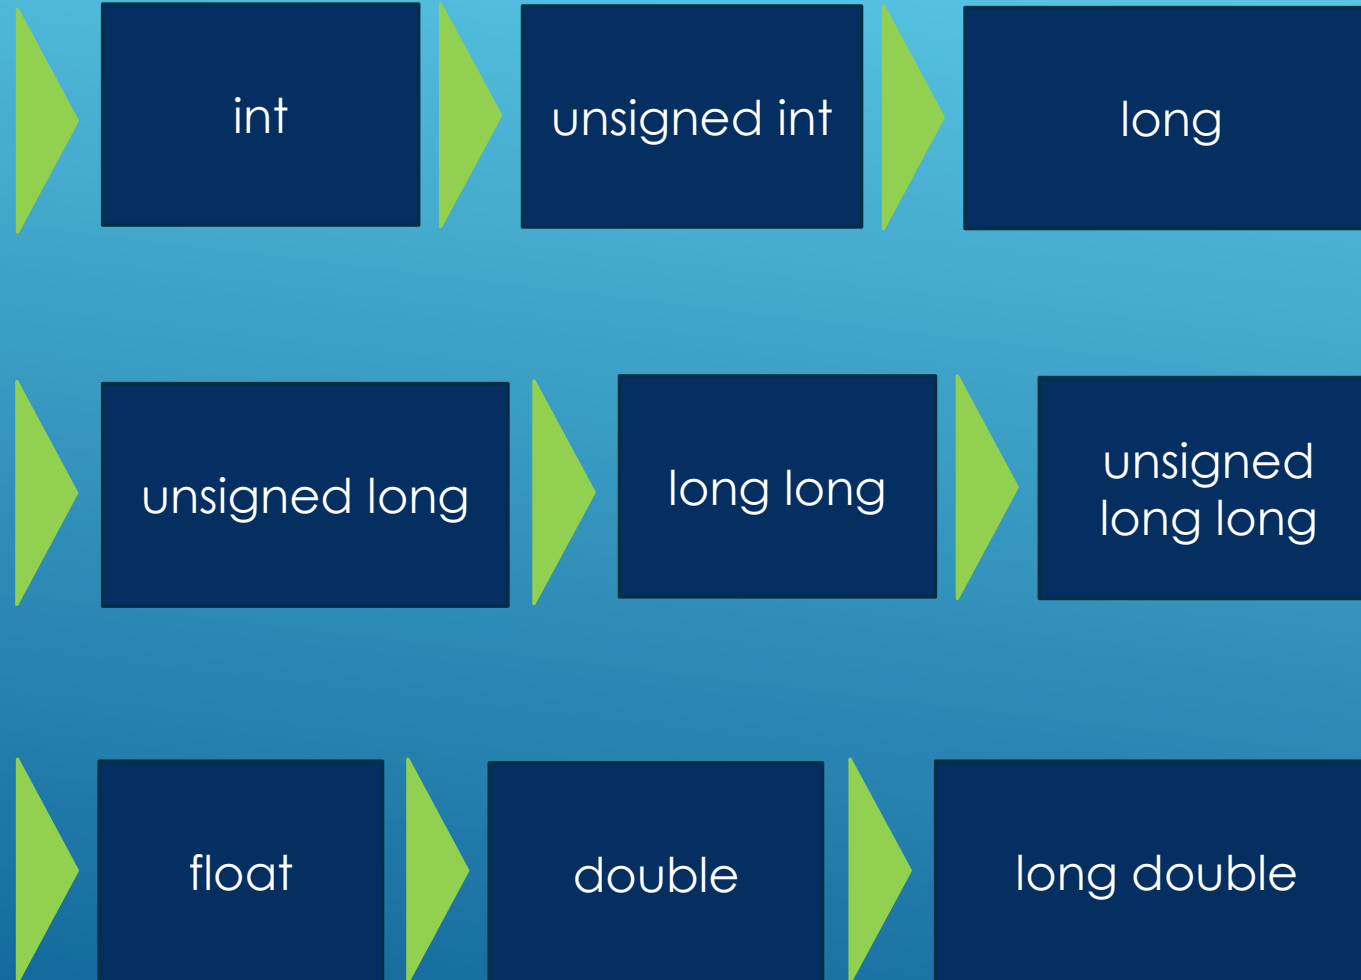

```
//      . The compiler applies implicit conversions
//      when types are different in
//      an expression
//      . Conversions are always done from the smallest
//      to the largest type in this case int is
//      transformed to double before the expression
//      is evaluated.Unless we are doing an assignment

double price { 45.6 };
int units {10};

double total_price = price * units;

std::cout << "Total price : " << total_price << std::endl;
std::cout << "sizeof total_price : " << sizeof(total_price) << std::endl;
```

## Conversion Guideline

```
//Implicit conversions in assignments

// The assignment operation is going to cause an implicit
// narrowing conversion , y is converted to int before assignment
int x;
double y {45.44};
x = y;
std::cout << "The value of x is : " << x << std::endl;
```

Slide intentionally left empty

# Explicit Data Conversions

int + int - int \* int + int

double + double - double \* double + double

Conversions are actively initiated by YOU! The developer.

## Implicit cast

```
//Implicit cast will add up the doubles,  
//then turn result into int for assignment  
double x { 12.5 };  
double y { 34.6};  
  
int sum = x + y;  
  
std::cout << "The sum is : " << sum << std::endl;
```

## static\_cast<>()

```
double x { 12.5 };  
double y { 34.6};  
  
//Explicitly cast : cast then sum up  
sum = static_cast<int>(x) + static_cast<int>(y) ;  
  
std::cout << "Cast then sum, result : " << sum << std::endl;
```

## static\_cast<>()

```
double x { 12.5 };  
double y { 34.6};  
  
int sum ;  
  
//Explicit cast : sum up then cast, same thing as implicit cast  
sum = static_cast<int> (x + y);  
std::cout << "Sum up then cast, result : " << sum << std::endl;
```

## Old style C-Cast

```
//Old style C-cast  
double PI {3.14};  
  
int int_pi = (int)(PI);  
std::cout << "PI : " << PI << std::endl;
```

## Prefer C++ casts over C- style casts

- C++ casts , `static_cast<>` is jut one of them, make your intent very clear
- They are easy to search for in code
- `Static_cast<>()` is checked by the compiler, and if the types are not compatible, you'll get a nice compiler error

# Overflow and Underflow

28

```
unsigned char char_var {55};
```

0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1
0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1
0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1
0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1
0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1
0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1
0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1
0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1
0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1
0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1
0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1
0	1	1	0	1	1	1	0	0	0	1	1	0	0	0	0	1	1	1	1	0	0	0	1	0	0	1	1	1	1	1

## Overflow

```
unsigned char char_var {55};  
  
unsigned char val1 {130};  
unsigned char val2 {131};  
  
char_var = val1 + val2;  
  
std::cout << "char_var : " << static_cast<int>(char_var) << std::endl;
```

## Overflow

...  
11111101 (253 dec)  
11111110 (254 dec)  
11111111 (255 dec)

Reset all bits  
00000000 (000 dec)  
00000001 (001 dec)

## Underflow

```
unsigned char char_var {55};

unsigned char val1 {130};
unsigned char val2 {131};

char_var = val1 - val2; // Underflow
std::cout << "char_var (exp -1) : " << static_cast<int>(char_var) << std::endl;
```

```
unsigned char char_var {55};  
char_var = 261; // Store in more than can fit in memory : Overflow  
char_var = -1; // Store in a negative number : Underflow
```

## General Thoughts

- Overflow and underflow are not only limited to char or integral types in general.
- It happens even on floating types, it was just easier to demonstrate it using the smallest possible integral type we can get our hands on : char. We just made it unsigned to , again, make it easier to demonstrate underflow
- As a general guideline, always be mindful of the valid range for the values you assign to the fundamental types we've learnt about. If in doubt, the <numeric> header has utilities you can use to query the limits for your types
- The compiler will sometimes throw warnings about overflows and underflows in your code. Keep an eye out for that
